4491 - In a Crazy City

Asia - Wuhan - 2009/2010

I live in a crazy city full of crossings and bidirectional roads connecting them. On most of the days, there will be a celebration in one of the crossings, that's why I call this city crazy.

Everyday, I walk from my home (at crossing s) to my office (at crossing t). I don't like crowds, but I don't want to waste time either, so I always choose a shortest path among all possible paths that does not visit the crossing of the celebration. If no such path exists, I don't go to work (it's a good excuse, isn't it)!

In order to analyze this ``celebration effect" in detail, I need n pairs of values (l_i, c_i), where l_i is the length of the shortest path from crossing s to crossing t, not visiting crossing i, c_i is the number of such shortest paths (not visiting crossing i). Could you help me? Note that if I can't go to work when celebration is held at crossing i, define $l_i = c_i = 0$. This includes the case when there is no path between s and t even if there's no celebration at all.

Ah, wait a moment. Please don't directly give me the values - that'll drive me crazy (too many numbers!). All I need is finding some interesting conclusions behind the values, but currently I've no idea what exactly I want.

Before I know what you should calculate, please prove that you can indeed find all the pairs (l_i, c_i) by telling me the value of $f(x) = (l_1 + c_1x + l_2x^2 + c_2x^3 + l_3x^4 + c_3x^5 + ... + l_nx^{2n-2} + c_nx^{2n-1}) \bmod 19880830$, for some given x.

Input

There will be at most 20 test cases. Each case begins with 5 integers n, m, s, t, q ($1 \leq s, t \leq n \leq 100,000$, $0 \leq m \leq 500,000$, $1 \leq q \leq 5$). n is the number of crossings, m is the number of roads and q is the number of queries. s and t are different integers that represent my home and office, respectively. Each of the following m lines describes a road with three integers: u, v, w ($1 \leq u, v \leq n$, $1 \leq w \leq 10,000$), indicating a bidirectional road connecting crossing u and crossing v, with length w. There may be multiple roads connecting the same pair of crossings, but a road cannot be connecting a crossing and itself. The next line contains q integers x_i ($1 \leq x_i \leq 10^9$). The last test case is following by five zeros, which should not be processed.

Output

For each test case, print the case number and q integers $f(x_1), f(x_2), ..., f(x_q)$ separated by a single space between consecutive items, on one line. Print a blank line after the output of each test case.

Explanation

In the first sample, $l_1 = c_1 = 0$, $l_2 = 4$, $c_2 = 2$, $l_3 = 3$, $c_3 = 1$, $l_4 = c_4 = 0$. In the second sample, everything is zero.

Sample Input

```
4 5 1 4 2
1 2 1
1 3 1
2 4 2
3 4 3
1 4 4
1 10
3 2 1 3 1
1 2 12
2 3 2
1
0 0 0 0 0
```

Sample Output

```
Case 1: 10 132400
Case 2: 0
```
